What is a Graph?

# What is a Graph?

$$G = \{V, E\}$$

- A graph represents the relation (*edges*) between a collection of entities (*nodes*).
- $V$  Vertices or nodes
- $E$  Edges or links
- $G$  Graph

**V** Vertex (or node) embedding

e.g., node identity, number of neighbors

**E** Edge (or link) embedding

e.g., edge identity, edge weight

**U** Global (or master node) embedding

e.g., number of nodes, longest path

Where to Find them?

**Graphs are all around us;** real world objects are often defined in terms of their connections to other things.

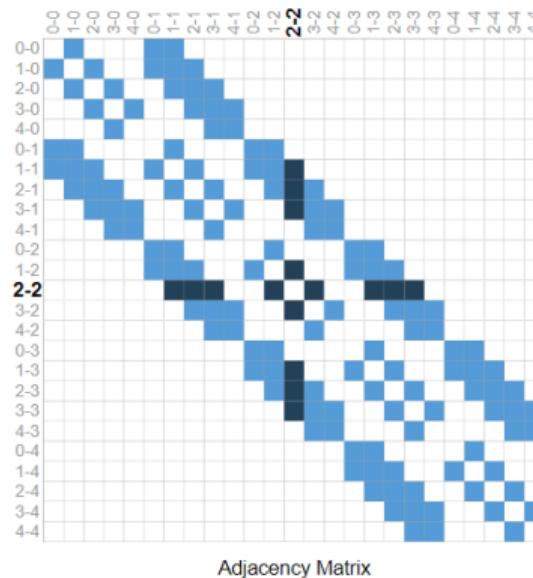

## Where to Find them?

The challenges of using graphs in ML

How do we go about solving these different graph tasks with neural networks?

The challenges of using graphs in ML

# How to Represent Graphs

Graphs have 4 types of information:

- nodes,
- edges,
- global-context,
- and connectivity!

The challenges of using graphs in ML

# How to Represent Graphs

Graphs have 4 types of information:

- nodes,
- edges,
- global-context,
- and **connectivity!**

$$N = \{node_i\} \quad [n_{nodes}, node_{dim}]$$

$$E = \{edge_i\} \quad [n_{edges}, edge_{dim}]$$

$$U = \text{master node's embedding} [, global_{dim}]$$

The challenges of using graphs in ML

# Representing Graph's Connectivity

- One elegant way to represent graphs is as **Adjacency lists**: These describe the connectivity of edge  $e_k$  between nodes  $n_i$  and  $n_j$  as a tuple  $(i, j)$  in the  $k$ -th entry of an adjacency list.
  - memory-efficient (even with sparse matrices),
  - permutation invariant.

The challenges of using graphs in ML

# Representing Graph's Connectivity

Images/adjacency-list.png

The simplest GNN

- **GNNs = Graph Neural Networks**
- **A GNN is an optimizable transformation on all attributes of the graph** (i.e., nodes, edges, global-context) **that preserves graph symmetries** (connectivity or permutation invariances)
- **"graph-in, graph-out"** architecture

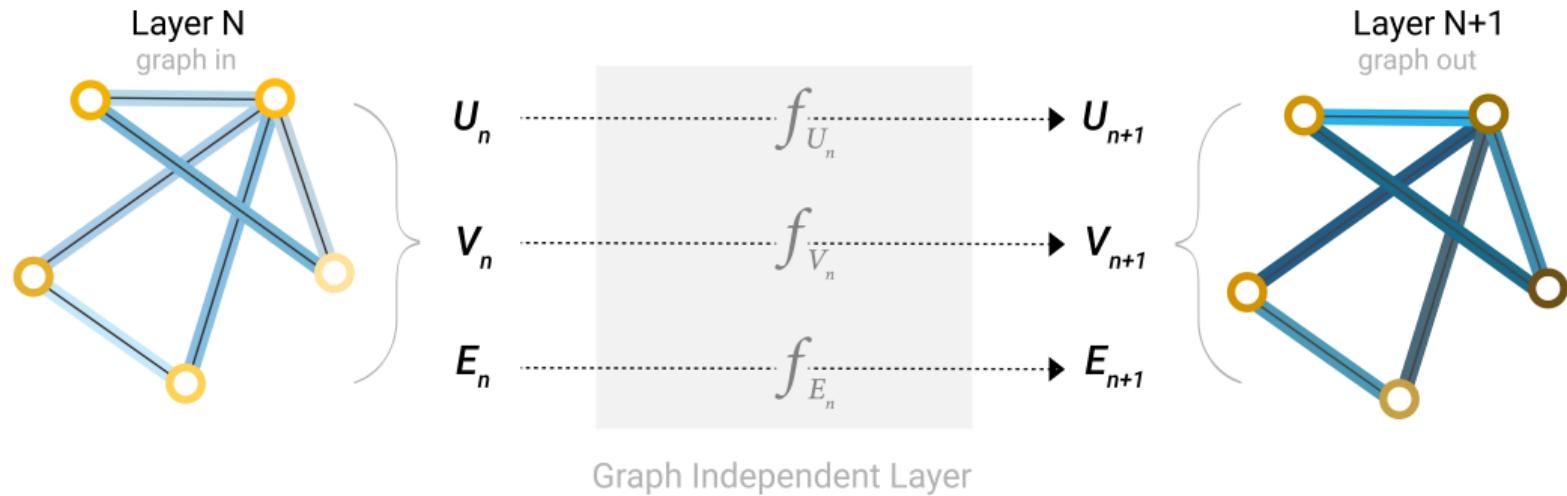

The simplest GNN

# The Simplest GNN

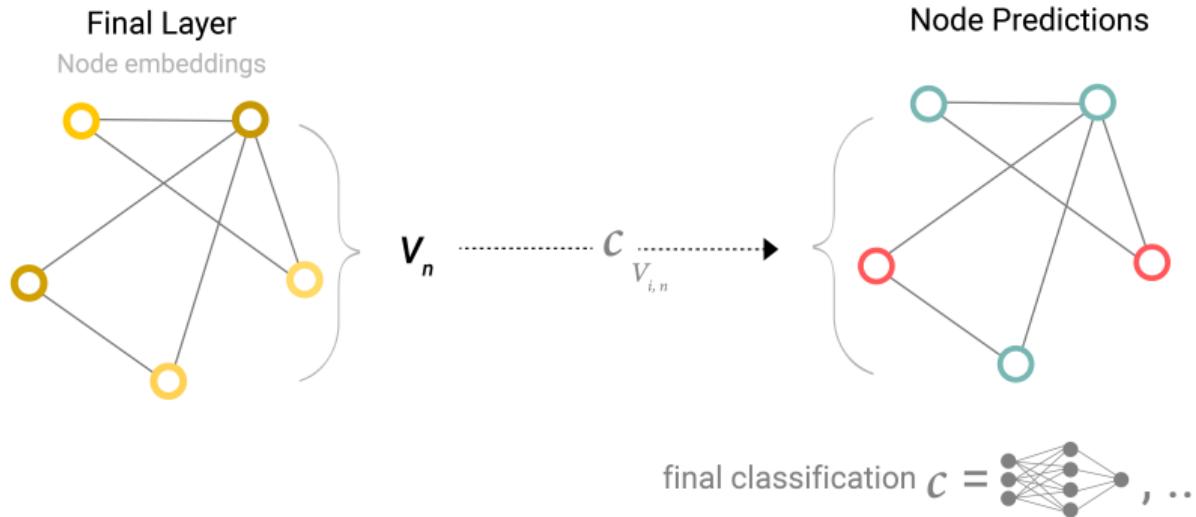

update function  $f = \text{[neural network diagram]}, \dots$

GNN Predictions by Pooling Information

# GNN Predictions

# Pooling Information

- **Pooling:** Collecting information from 1 component and giving them to another.

# Pooling Information

- **Pooling:** Collecting information from 1 component and giving them to another.
  - ➊ For each item to be pooled, *gather* each of their embeddings and concatenate them into a matrix.

# Pooling Information

- **Pooling:** Collecting information from 1 component and giving them to another.

- ① For each item to be pooled, *gather* each of their embeddings and concatenate them into a matrix.
- ② The gathered embeddings are then *aggregated*, using via a operation (e.g., sum, mean).

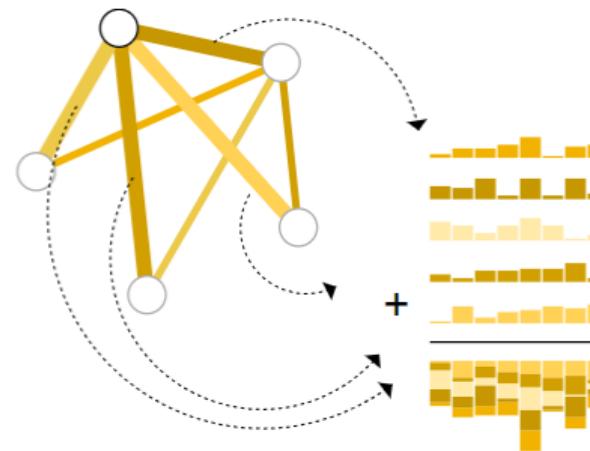

# Pooling Information

- **Pooling:** Collecting information from 1 component and giving them to another.
  - 1 For each item to be pooled, *gather* each of their embeddings and concatenate them into a matrix.
  - 2 The gathered embeddings are then *aggregated*, using via a operation (e.g., sum, mean).
- Abbreviation:  $\rho$  e.g., gathering information from edges to nodes  $\rho_{E_n \rightarrow V_n}$ .

# Pooling Information

Aggregate information  
from adjacent edges

# End2End Prediction Task with a GNN Model

GNN Predictions by Pooling Information

# End2End Prediction Task with a GNN Model

- We still don't use the connectivity of the graph
  - Each component is processed independently
  - ONLY use connectivity when prediction

Passing messages between parts of the graph

...What if we try using pooling inside GNN Layers?

Passing messages between parts of the graph

...What if we try using pooling inside GNN Layers?

Or to make our learned embeddings aware of graph **connectivity**?

Passing messages between parts of the graph

# Message Passing

- **Message Passing:**

- ① For each node in the graph, *gather* all the neighboring node embedding (or messages), which is the  $g$  function described above.
  - ② *Aggregate* all messages via an aggregate function (e.g, sum).
  - ③ All pooled messages are passed through an *update function*, usually a learned neural network.
- Just as pooling can be applied to either nodes or edges, message passing can occur between either nodes or edges.

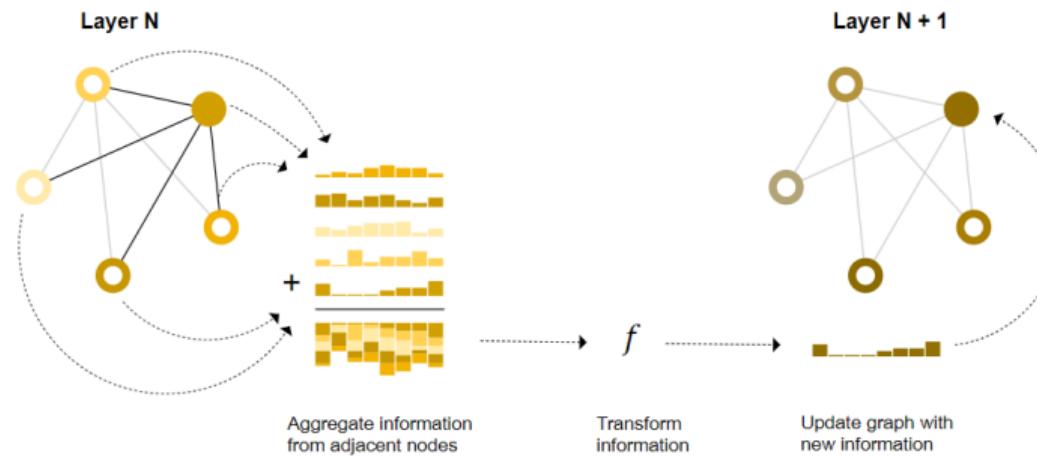

Passing messages between parts of the graph

# Learning Edge Representations

update function  $f = \text{[neural network]}, \dots$   
 pooling function  $\rho$

Passing messages between parts of the graph

# Adding Global Representations

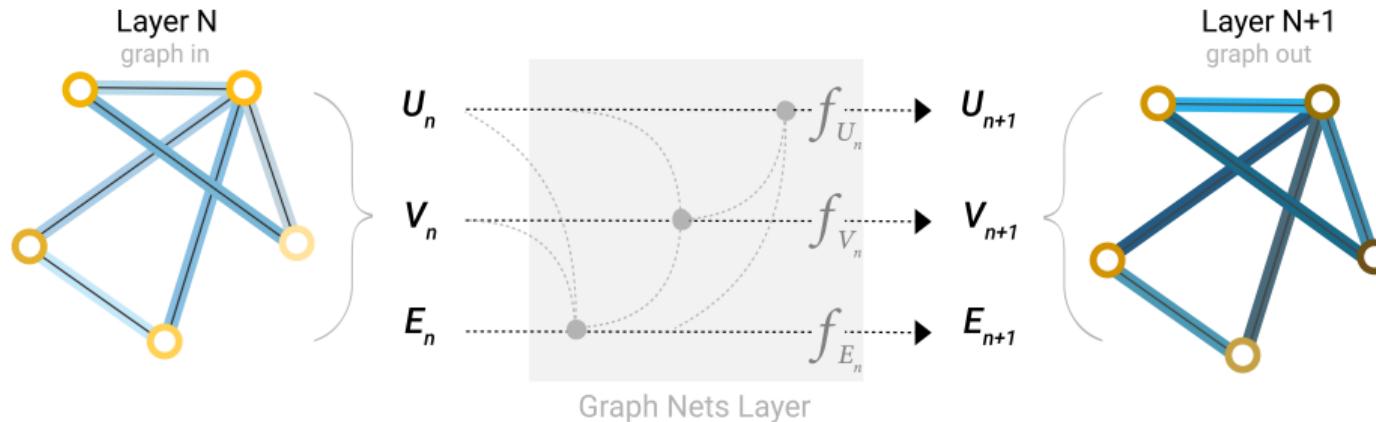

- So far, there is still one flaw:
  - Nodes that far away from each other in the graph may never be able to efficiently transfer information to one another, even which several layers.
  - e.g., if we have  $k$ -layers, information will propagate at most  $k$ -steps away.
- One solution is by using the global representations or **master node**.

  - calculate on randomized but **constant** size subsets of the training data (mini-batches).
  - Sometimes, a graph is too large that it cannot be fit in memory.

## Sampling Graphs and Batching in GNNs

- For training neural networks, it's common to:
  - calculate on randomized but **constant** size subsets of the training data (mini-batches).
- Sometimes, a graph is too large that it cannot be fit in memory.
- However, the number of nodes and edges adjacent to each other are variable.

# Sampling Graphs

- To create subgraphs that preserve essential properties of the larger graph.
- This graph sampling operation is highly dependent on context,
  - some might make sense in some contexts (citation networks),
  - but might be too strong of an operation in others (molecule graph).
- Cluster-GCN, GraphSaint, Metropolis algorithm, etc...
